Group Contribution Journal

ITAI 1371 | Lab 06: Regression and Classification | NeuralCrew

Patrick Ray

For my individual contribution to Lab 6, I completed the Linear Regression and Logistic Regression exercises in the notebook. I trained and evaluated both models, generated the required predictions, printed and interpreted the Linear Regression coefficients, and completed the Knowledge Check questions. I also worked through the errors that occurred while processing the classification data and verified the completed notebook by running the required cells successfully. My completed work will be combined with the contributions of the other NeuralCrew team members for the group submission.

Viviana Zamora

I completed and tested the Linear Regression and Logistic Regression portions of Lab 06. I corrected formatting issues in the provided notebook code, trained and evaluated both models, reviewed the model outputs and coefficients, and completed the knowledge-check questions explaining regression, classification, coefficients, mean squared error, and accuracy.

Funsho Orogun

During the lab, I encountered several syntax-related errors while setting up the required Python libraries. The first issue occurred when multiple import statements were accidentally combined into a single line, which resulted in a SyntaxError: invalid syntax message.

For example, statements such as import pandas as pdfrom sklearn.model_selection… were interpreted as one continuous command, making it impossible for Python to correctly parse the code. After reviewing the error, I resolved the issue by placing each import and from ... import ... statement on its own separate line.

A similar problem occurred later when two scikit-learn imports were combined without proper spacing or line breaks, such as from sklearn.linear_model import LogisticRegressionfrom sklearn.metrics import accuracy_score.

Recognizing that Python requires clear separation between commands, I reformatted the setup cell so that each library import appeared on its own line before execution. These troubleshooting experiences reinforced the importance of proper code formatting, careful attention to syntax, and organized programming practices when working with machine learning and data science workflows.

Dustin Mastrota (Levi)

My contribution to this notebook was completing the linear regression and logistic regression tasks in Google Colab. I created and trained a linear regression model to predict Titanic passenger fares using age and passenger class, made predictions on the test data, and evaluated the results using mean squared error. I also created and trained a logistic regression model to predict survival using age, passenger class, and sex, then evaluated its predictions using accuracy. In addition to completing the model code, I answered the knowledge check questions about the differences between regression and classification, the meaning of the linear regression coefficients, and why each model uses a different evaluation metric.

Compiled from the four members' submitted contribution accounts. Descriptions preserve each member's reported work.
